

OWLBOARD JR

Assembly and programming

Kevin Pintong

The owlboard JR is based on the reference design and source code used in the 'DIY ChipKit board'. It is programmable

<http://chipkit.net/diy-chipkit-board>

Features:

- Uses 32-bit PIC microcontroller PIC32MX250F128B in SPDIP-28 package with preprogrammed bootloader.

- USB connector built into PCB for easy programmability (Detected as a stk500 programmer).

- Increased PCB thickness for USB connector (2.0mm)

- 19 GPIO pins

In order to build the OwlBoard Jr, you will be using soldering equipment, solder, and flux. Soldering equipment will be extremely hot. Solder and flux may contain hazardous substances such as lead.

It is advised that the participant:

Resistors, capacitors, connectors, sockets on this design are non-polarized. You may insert them in any direction.

PIC32 microprocessor must be oriented as shown in Figure 17 Fully assembled Owlboard Jr. The yellow dot must be oriented towards D1.

Buttons will only fit in one direction. Do not attempt to force 0 0 1 36 70k rds D1.

1. Plug your board into the computer while holding down the button marked 'SW'. Let go after the board is inserted. The SW button is the program button. On this revision of the board, the program button and 'SW' buttons were swapped.
2. The right LED should rapidly start blinking indicating that it is in bootloader mode.
3. When you wish to reprogram the board, hold the 'SW' button down before inserting.
4. If you do not hold the button down, your code will run on the board.

Navigate to the extracted folder and launch MPIDE.

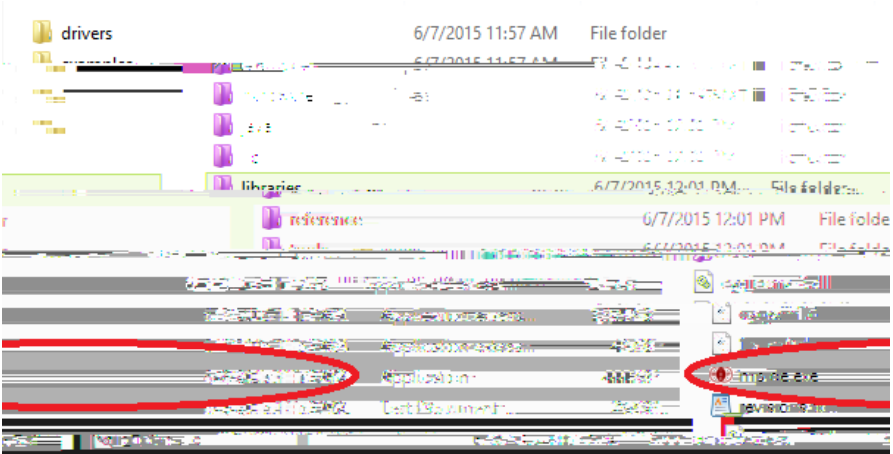

Figure 19 Launch MPIDE

Verify that the DP32 board is selected. This board most closely matches the owlBoard Jr.

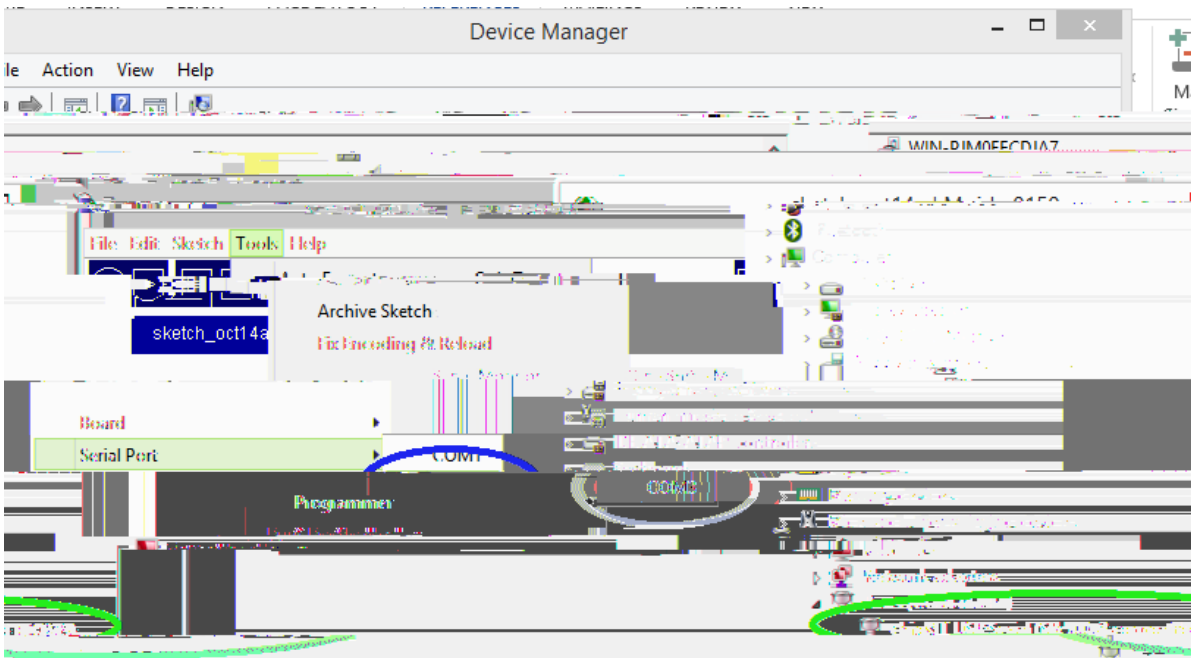

Figure 20 Verify DP32 is selected

Verify that the correct COM port is selected.
